Convergent-type dendrimers are interesting macromolecules which possess a well-defined structure. Furthermore, their size, shape and functionality can be modulated by synthesis, generation by generation.

We have demonstrated that grafting liquid-crystalline dendrimers onto various active or reactive three dimensional architectures, including fullerene,<sup>1</sup> fullerene-ferrocene<sup>2</sup> and dinuclear ruthenium complexes,<sup>3</sup> is an effective and elegant way to control the mesomorphic behavior of the materials and the structure of the mesophases.

We discuss, here, the structure-supramolecular organization relationship for the above-mentioned materials. One example is presented below ( $T_g$ : not detected,  $Col_r$  99  $Col_r$  150  $Col_h$  157 I).
